Abstract of the Disclosure

This invention falls into the field of devices designed to prevent medical workers after using needles on patients who may be suffering from infective pathologies transmissible via blood. A protective element is composed, at the time of production and shipping, of a first portion and a second portion reciprocally constrained by a connecting element moulded contemporaneously with the said two portions. A pan has been created inside the first portion and first ridges and second ridges have been created in the lower part of the second portion.
